Histogram of Oriented Gradients and Object Detection

by Adrian Rosebrock on November 10, 2014 in Machine Learning, Tutorials

If you've been paying attention to my Twitter account lately, you've probably noticed one or two teasers of what I've been working on — a Python framework/package to rapidly construct object detectors using Histogram of Oriented Gradients and Linear Support Vector Machines.

Honestly, I really can't stand using the Haar cascade classifiers provided by OpenCV (i.e. the Viola-Jones detectors) — and hence why I'm working on my own suite of classifiers. While cascade methods are extremely fast, they leave much to be desired. If you've ever used OpenCV to detect faces you'll know exactly what I'm talking about.

Figure 1: Example of falsely detecting a face in an image. This is a common problem when using cv2.detectMultiScale.

In order to detect faces/humans/objects/whatever in OpenCV (and remove the false positives), you'll spend a lot of time tuning the cv2.detectMultiScale parameters. And again, there is no guarantee that the exact same parameters will work from image-to-image. This makes batch-processing large datasets for face detection a tedious task since you'll be very concerned with either (1) falsely detecting faces or (2) missing faces entirely, simply due to poor parameter choices on a per image basis.

There is also the problem that the Viola-Jones detectors *are nearing 15 years old*. If this detector were a nice bottle of Cabernet Sauvignon I might be pretty stoked right now. But the field has advanced substantially since then. Back in 2001 the Viola-Jones detectors were state-of-the-art and they were certainly a huge motivating force behind the incredible new advances we have in object detection today.

Now, the Viola-Jones detector isn't our only choice for object detection. We have object detection using keypoints, local invariant descriptors, and bag-of-visual-words models. We have Histogram of Oriented Gradients. We have deformable parts models. Exemplar models. And we are now utilizing Deep Learning with pyramids to recognize objects at different scales!

All that said, even though the Histogram of Oriented Gradients descriptor for object recognition is nearly a decade old, it is still heavily used today — and with fantastic results. The Histogram of Oriented Gradients method suggested by Dalal and Triggs in their seminal 2005 paper, *Histogram of Oriented Gradients for Human Detection* demonstrated that the Histogram of Oriented Gradients (HOG) image descriptor and a Linear Support Vector Machine (SVM) could be used to train highly accurate object classifiers — or in their particular study, human detectors.

Histogram of Oriented Gradients and Object Detection

I'm not going to review the entire detailed process of training an object detector using Histogram of Oriented Gradients (yet), simply because each step can be fairly detailed. But I wanted to take a minute and detail the general algorithm for training an object detector using Histogram of Oriented Gradients. It goes a little something like this:

Step 1:

Sample *P* positive samples from your training data of the object(s) you want to detect and extract HOG descriptors from these samples.

Step 2:

Sample N negative samples from a *negative training set* that **does not contain** any of the objects you want to detect and extract HOG descriptors from these samples as well. In practice N >> P.

Step 3:

Train a Linear Support Vector Machine on your positive and negative samples.

Step 4:

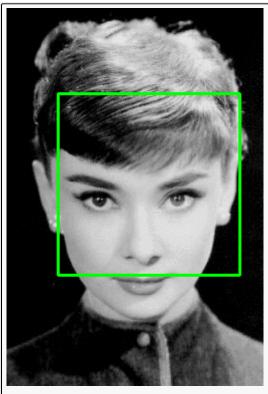

Figure 2: Example of the sliding a window approach, where we slide a window from left-to-right and top-to-bottom. Note: Only a single scale is sown. In practice this window would be applied to multiple scales of the image.

Apply hard-negative mining. For each image and each possible scale of each image in your negative training set, apply the sliding window technique and slide your window across the image. At each window

compute your HOG descriptors and apply your classifier. If your classifier (incorrectly) classifies a given window as an object (and it will, there will absolutely be false-positives), record the feature vector associated with the false-positive patch along with the probability of the classification. **This approach is called** *hard-negative mining.*

Step 5:

Take the false-positive samples found during the hard-negative mining stage, sort them by their confidence (i.e. probability) and re-train your classifier using these hard-negative samples. (Note: You can iteratively apply steps 4-5, but in practice one stage of hard-negative mining usually [not not always] tends to be enough. The gains in accuracy on subsequent runs of hard-negative mining tend to be minimal.)

Step 6:

Your classifier is now trained and can be applied to your test dataset. Again, just like in Step 4, for each image in your test set, and for each scale of the image, apply the sliding window technique. At each window extract HOG descriptors and apply your classifier. If your classifier detects an object with sufficiently large probability, record the bounding box of the window. After you have finished scanning the image, apply non-maximum suppression to remove redundant and overlapping bounding boxes.

These are the bare minimum steps required, but by using this 6-step process you can train and build object detection classifiers of your own! Extensions to this approach include a deformable parts model and Exemplar SVMs, where you train a classifier for *each positive instance* rather than a *collection of them*.

However, if you've ever worked with object detection in images you've likely ran into the problem of detecting multiple bounding boxes around the object you want to detect in the image.

Here's an example of this overlapping bounding box problem:

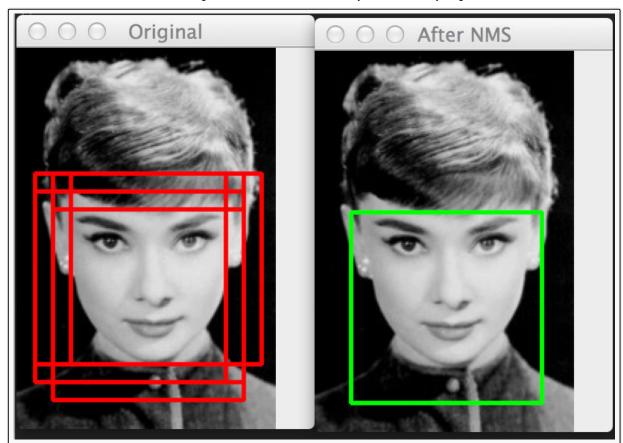

Figure 3: (*Left*) Detecting multiple overlapping bounding boxes around the face we want to detect. (*Right*) Applying non-maximum suppression to remove the redundant bounding boxes.

Notice on the *left* we have 6 overlapping bounding boxes that have correctly detected Audrey Hepburn's face. However, these 6 bounding boxes all refer to the same face — we need a method to suppress the 5 smallest bounding boxes in the region, keeping only the largest one, as seen on the *right*.

This is a common problem, no matter if you are using the Viola-Jones based method or following the Dalal-Triggs paper.

There are multiple ways to remedy this problem. Triggs et al. suggests to use the Mean-Shift algorithm to detect multiple modes in the bounding box space by utilizing the (x, y) coordinates of the bounding box as well as the logarithm of the current scale of the image.

I've personally tried this method and wasn't satisfied with the results. Instead, you're much better off relying on a *strong classifier* with *higher accuracy* (meaning there are very few false positives) and then applying non-maximum suppression to the bounding boxes.

I spent some time looking for a good non-maximum suppression (sometimes called non-maxima suppression) implementation in Python. When I couldn't find one, I chatted with my friend Dr. Tomasz Malisiewicz, who has spent his entire career working with object detector algorithms and the HOG descriptor. There is literally *no one* that I know who has more experience in this area than Tomasz. And if you've ever read any of his papers, you'll know why. His work is fantastic.

Anyway, after chatting with him, he pointed me to two MATLAB implementations. The first is based on the work by Felzenszwalb et al. and their deformable parts model.

The second method is implemented by Tomasz himself for his Exemplar SVM project which he used for his dissertation and his ICCV 2011 paper, *Ensemble of Exemplar-SVMs for Object Detection and Beyond*. It's important to note that Tomasz's method *is over 100x faster* than the Felzenszwalb et al. method. And when you're executing your non-maximum suppression function millions of times, that 100x speedup really matters.

I've implemented both the Felzenszwalb et al. and Tomasz et al. methods, porting them from MATLAB to Python. Next week we'll start with the Felzenszwalb method, then the following week I'll cover Tomasz's method. While Tomasz's method is substantially faster, I think it's important to see both implementations so we can understand exactly *why* his method obtains such drastic speedups.

Be sure to stick around and check out these posts! These are absolutely critical steps to building object detectors of your own!

Summary

In this blog post we had a little bit of a history lesson regarding object detectors. We also had a sneak peek into a Python framework that I am working on for object detection in images.

From there we had a quick review of how the Histogram of Oriented Gradients method is used in conjunction with a Linear SVM to train a robust object detector.

However, no matter what method of object detection you use, you will likely end up with multiple bounding boxes surrounding the object you want to detect. In order to remove these redundant boxes you'll need to apply Non-Maximum Suppression.

Over the next two weeks I'll show you two implementations of Non-Maximum Suppression that you can use in your own object detection projects.

Be sure to enter your email address in the form below to receive an announcement when these posts go live! Non-Maximum Suppression is absolutely *critical* to obtaining an accurate and robust object detection system using HOG, so you definitely don't want to miss these posts!

Non-Maximum Suppression for Object Detection in Python >

152 Responses to Histogram of Oriented Gradients and Object Detection

SHI Xudong November 10, 2014 at 11:20 pm #

Hi Adrian,

Thank you for your great post.

I am currently working on object detection too. My goal is to make the detection faster, because object detectors are usually slow.

In your post, the object detection framework you are using is a 1 model, N image scales. However, there are alternatives, such as N models, 1 image scale; 1 model, N/K (K > 1) image scales (FPDW approach); N/K models (K > 1), 1 image scale.

I am thinking about creating a unified framework, which can include all these frameworks, but have no idea about the implementation now. Could you please make some comments:

- Is it worth to try?
- how will you do if you are doing it?

References:

- 1. Benenson, Rodrigo, et al. "Pedestrian detection at 100 frames per second." Computer Vision and Pattern Recognition (CVPR), 2012 IEEE Conference on. IEEE, 2012.
- 2. Dollár, Piotr, Serge Belongie, and Pietro Perona. "The Fastest Pedestrian Detector in the West." BMVC. Vol. 2. No. 3. 2010.

Hi Shi! You are absolutely right, object detectors can be painfully slow, especially when you using the sliding window technique. And when expensive features such as HOG need to be computed, it can really kill performance.

And you are correct, I am utilizing the N image scales model for this framework. However, I have plans to create something similar to the FPDW approach by Dollar et al.

Right now performance using the N image scales model is actually pretty good for my framework, but not great. The reason is because I have distributed the image pyramid to all available cores of the system — this is an obvious solution where making the HOG sliding window computation run in parallel can dramatically speedup the code.

However, doing something like FPDW will further increase the speed (but lessen accuracy slightly).

Send me an email and I would be happy to chat more about implementation details. Thanks again for the comment, there is a ton of great information in here.

Niv November 17, 2014 at 9:29 am #

REPLY 🦴

Nice post, thanks.

In phase #5, the false positives are taken along with their probabilities and then sorted by their probabilities in order to further retrain the classifier. I have two questions about which I would appreciate to get a clarification:

- 1. why do you need their probabilities in that retraining phase? linear SVM doesn't require their probabilities but rather merely their taggings (negatives in this case).
- 2. Why do you need them to be sorted? linear SVM doesn't require any sorting of the training samples.

Adrian Rosebrock November 17, 2014 at 10:49 am

REPLY 🦴

You would want to keep track of the probabilities for two reasons. The first being that you may not have enough physical memory to store the positive samples, negative samples, and hard-negative samples and train your SVM. In the case you are limited by RAM, you would want to sort the samples by their probability and keep only the samples the classifier performed "worst" on, discarding the rest. Secondly, you may be worried about overfitting.

Will Steps 4 and 5 work for a multiclass cascade classifier as well, that uses a boosting algorithm? I notice in your example you're dealing with LSVMS.

Adrian Rosebrock December 18, 2014 at 7:45 am #

REPLY 🦴

Potentially, but there are other approaches that are more robust (and faster to train) than cascade classifiers.

Karthik January 6, 2015 at 1:33 am #

REPLY 🦴

According to the paper published by Dalal and Triggs, they suggest gamma correction is not necessary. I have the doubt about whether correcting gamma is a good option to go for or not. If Gamma correction is necessary what is the gamma value I have to take for better performance. Awaiting for reply.!!! thanks in advance!!

Adrian Rosebrock January 6, 2015 at 7:38 am

REPLY 🦴

That is correct, gamma correction is not necessary. Normalization however is quite often helpful. You can normalize by either taking the log or the square-root of the image channel before applying the HOG descriptor (normally the square-root is used). Another method to make HOG more robust is to compute the gradient magnitude over all channels of the RGB or L*a*b* image and take the maximum gradient response across all channels before forming the histogram.

Karthi January 6, 2015 at 2:40 pm #

REPLY 🦴

Thank you for your reply!! But why can't we consider converting to grayscale and processing would be the better option?

Adrian Rosebrock January 6, 2015 at 2:52 pm

REPLY 🦴

You can certainly convert to grayscale and compute HOG as well. It's just been shown that taking the maximum response over the individual RGB or L*a*b* channels can increase accuracy in some cases. Your mileage may vary depending on your dataset.

Karthik January 6, 2015 at 3:45 pm #

And we are actually stretching the contrast while we are gamma correcting, so which gamma value you think will be providing the higher performance? gamma of 2?

Adrian Rosebrock January 6, 2015 at 4:02 pm #

Please see my previous comment. I would not recommend using gamma correction. Just a simple log or square-root normalization should suffice.

Sarah April 10, 2015 at 11:34 pm #

REPLY 🦴

In opency the gamma correction can only be set or not set. I wonder what is the valued applied by default. For images which can be taken at night. I believe gamma correction might help?

REPLY 🦴

Hi Sarah, thanks for the comment. However, log-based gamma correction normally hurts HOG + Linear SVM performance. The square-root (in most cases) or simple variance normalization is better option.

I have a suggestion for speeding up the search, and would like your opinion.

What if you applied the KPM, or Boyer-Moore to the search? Meaning, convert the histogram 'coefficients' to a string representation, and do the same with the image being searched. Then, look at the 'suffixes' first.

I've used the Boyer-Moore, because it's about 10x faster for string searching. In this application, it would be like looking at the right edge of a rect first, and then skipping over pixels when there isn't a match.

REPLY 🦴

Hi , i'am working at detection face and i have a problem. the algorithm didn't detect the faces in in different position. what's the problem ?

Thank you

REPLY 🦴

Hi Miriam. Unfortunately, there could be many, many reasons why faces are not detected and your question is a bit ambiguous. Here are just some example questions for you to consider: Are you using HOG + Linear SVM? Have you chosen the optimal HOG parameters for your descriptor? What about your Linear SVM? Are you using a soft-classifier? Do your training examples sufficiently represent the faces that you want to detect in images? Are you performing hard negative mining to increase accuracy? Are you using image pyramids so you can detect faces at multi-scales? Or using a sliding window so detect faces in different positions of the image? Be sure to consider all avenues.

You'll need to modify my NMS code to accept a list of probabilities that corresponds to the bounding boxes. Then you'll need to sort those probabilities (Line 27) rather than the bottom-right corner.

Rish April 23, 2015 at 12:42 pm #

Hi Adrian. Thank you very much I managed to get it working with LibSVM. However, I noticed that getting the probabilities from SVM is computationally more expensive compared to the label prediction (hard decision). I wonder if this happens or did I just got something wrong? Mathematically, I think estimating probability needs more operations. However, my question here is that if I dont use probability but just use label predication i.e (+1/-1) than use yoFree 21-day crash course onegion, do you think that is also good enough or Probacomputer vision & image search roves results? (Apologies my poor English) engines

Secondly, about the HOG descriptor. Say for example I trained standing bottle (say sliding window of 64 x 128) = 3780 dimension feature vector. During detection, I will use this window size to detect the bottle. However, my question is when the bottle is resting on its side (now say the dimesion is 128 x 64) but our detector uses the window of 64 x 128, how do I cater for this issue? I read paper on Part based model but I think PBM is computationally expensive. Perhaps I thought to divide the training image into 4 parts (say 16 x 32) and train this. Do you have any suggestion on this?

Adrian Rosebrock April 23, 2015 at 1:08 pm

Hey Rish, you're absolutely computational cost. However, if you precise final bounding boxes. It really tolerance you're willing to accept.

As for your second question, HOG b there is a certain "structure" to the in recognize a bike, it would look for tw were rotated 90 degrees, you would descriptors and hence in your case object is rotated.

Hi Adrian. Sorry I was busy with my Finals so was unable to complete my work. Actually, I have got most of the HOG detection implemented in C++. As I mentioned above, that I want to change your NMS from Bottom Right Corner to probability sorting as you mentioned.

I think I am bit lost, I removed all the bounding box params from your NMS and use the Probability instead I am confused like in line 51 where you done the overlapping computation. How can I change this to probability instead? Do I need to do something is Gradient Decent? Sorry I am just confused, please help me out. Thanks

Free 21-day crash course on computer vision & image search engines

No need for gradient descent or anything fancy. When you make a call to you

NMS function you'll need to pass in three variables, the bounding boxes, the overlap threshold, and a probability of detection that corresponds to the bounding box. Then you need to sort (from highest probability to lowest probability) the bounding boxes based on their probability. From there, everything will be the same. Like I said, the only code that you'll need to change is the code that sorts on probability rather than the bottom-right coordinate.

Siva Krishna January 30, 2016 at 5:08 am #

Hi Andrian,

I have few doubts regarding NMS algorithm using probabilities

- 1. What does probability means? It i it?
- 2. You said that we have to sort in d to sort in increasing order, since we

So basically, hard negative mining is all about fir HOG feature vectors) that the Linear SVM gets to pretend we are training an object detector to detect extract HOG features from a positive dataset (the negative dataset (which contains absolutely no feature train our Linear SVM.

becoming a computer vision master.

Email Address

LET'S DO IT!

However, this classifier may falsely detect faces in images where there are no faces. So, we run our classifier on the negative data (which contain no faces what-so-ever), and we collect any HOG feature vectors that the classifier incorrectly reports as a face. This process is called "hard-negative mining". In your case, if you get a false-positive from your trained classifier you want to *keep* that data since you can use it to better improve your classifier.

Finally, we need to re-train our classifier, which is just a 1-vs-1 SVM: either "face" or "not a face" using the HOG feature vectors from the original face dataset, the HOG feature vectors from the non-face dataset, as well as the hard-negative HOG feature vectors.

We then let this classifier train, with the end goal (normally) being that our classifier better detects faces, while ignoring non-faces.

Adrian Rosebrock July 7, 2015 at 1:31 pm #

REPLY 🦴

Simply put, a Linear SVM is very fast. A random forest classifier is capable of generalizing to non-linear spaces; however, it requires computing N number of trees. It also doesn't work well for sparse feature spaces which Linear SVMs excel at. SVMs can also return probability estimations as well.

2. HOG is indeed an image descriptor. You could certainly use any other image descriptor and feed it into your classifier, such as Local Binary Patterns, Zernike moments, Haralick texture.

And yes, you can AKAZE, BRISK, SURF, SIF creating a bag-of-visual-words prior to passic covering all of these topics in detail inside the played around with machine learning, Practic

REPLY 🤝

A semi-rigid object is something that has a clear form and structure, but can change slightly — consider how a human walks. We put one foot in front of the other, maybe move our arms a bit. The form is clearly the same, but it does change a little bit. HOG can be used to detect semi-rigid objects like humans provided that our poses are not too deviant from our training data. Finally, smoke is definitely not a semi-rigid object. Smoke diffuses into the air and has no real shape or form.

Shahab March 9, 2016 at 6:33 am #

REPLY 🦴

Hi Adrian.

Thank you so much for this perfect step-by-step instruction. I'm working on recognizing traffic signs using SVM + HOG. The algorithm is great and the accuracy is very reasonable; however, the speed is deriving me crazy. For each image, of hundreds, it takes more than 5 minutes to yield the results. I really need to shorten this time to at most a minute or less. The sliding window is the main problem. How can I handle the slow moving of sliding window? Thank you in advance.

Adrian Rosebrock March 9, 2016 at 4:39 pm

Free 21-day crash course on computer vision & image search engines

The sliding window itself isn't the actual problem — it's the time associated with extracting the HOG features and then passing them through the SVM. Your pyramid scale may also be hurting performance. I would suggest increasing the size of the image pyramid along with the step size of the sliding window as much as possible without hurting accuracy. The larger the pyramid scale and the sliding window step size are, the less window need to be evaluated.

Dmitry Zaytsev April 19, 2016 at 4:49 am

REPLY 🦴

What about training a Haar (well, LBP) cascade first, lowering false-negatives rate and not bothering much about false-positives. Then, instead of sliding the window just go through every object detected by cascade.

I didn't tried that myself, but maybe you did?

romanzo April 27, 2016 at 3:11 am #

Hi Adrian great post!

I'm trying to build my own SVM and detect object them on test image using hog.detectMultiScale. I tried to build a SVM classifier from sklearn and opency using crossvaligdation. It gives a good accuracy during the cross validation and also while using other test images (however the opency one just gives me one support vector which is kinda of weird).

If i use sklearn SVM, I load the coef_ attribute of my SVC object (which corresponds to the primal sv) using setSVMDetector but the detection gives a lot of false positive and not even a true positive on the images that were well detected with the sklearn predict...

Have you trained your own svm model and used it with detectMultiScale? Any ideas of what I could do wrong.

Thanks a lot!

If you want to train your own custom ob wouldn't recommend using OpenCV. I would inst PylmageSearch Gurus course. The Python + Op also don't have much control over the training process.

No problem Gabriel, I'm happy to help. I know I already mentioned this so I don't want to beat it to death, but I do demonstrate how to train your own HOG detector using sliding windows, image pyramids, and scikit-learns SVM module inside the PylmageSearch Gurus course. If you get stuck implementing on your own (or would like to learn from well documented tutorials) then I would definitely suggest taking a look at the course.

Hi Adrian.

Great site for OpenCV and Image Processing. I have some questions:

1. As you said in Step 2: Sample N negative sample contain" any of the objects you want to detect and e In practice N >> P.

Free 21-day crash course on computer vision & image search engines

So example if I want to train a smile detector, the positive images contain many smiling faces and the negative are not smile faces. It's mean that both positive and negative are include face, so is it contradict with: "does not contain"?

- 2. In case of smile detector, I want to make a classifier with 3-classes: normal opening mouth (not smile) – smile. I used Viola-Jones algorithm and it's not good. Now, i'm using Logistic Regression (opency) to make 2 binary classifier: normal – opening mouth, normal – smile. It's better than Viola-Jones, but it still get many false-positives. So in your experience, is that HOG+Linear SVM better? Or could you suggest any approach?
- 3. With HOG + Linear SVM Model or any Model you suggestion, can I save this model to re-use it in mobile, example save model as xml file and load it in Objective-C (iOS) or Java (Android)? So I'm just predict later, not training again. Finally, may I run rea

Adrian Rosebrock November 10, 2016 at 7:29 am #

REPLY 🦴

The number of extracted HOG features is entirely dependent on your dataset. A good rule of thumb is to have approximately 5-10x as many negatives as your positives and then perform hard-negative mining. As far as a kernel goes, a linear kernel tends to be standard due to how fast it is. Given your current dataset I would suggest performing an initial experiment to obtain a baseline. From there you can try adjusting the number of negatives and hard-negatives.

Gerardo Rosiles November 10, 2016 at 2:07 pm

Hi Adrian.

Regarding the detection performance. How do you of classifiers using metrics like precision and recall?

It seems to me you need to first evaluate the classifi measure the discriminative ability of the classifier ar other way.

My impression is that the detector feeds a very large giving you lots of true negatives and a few (or none) the actual object (which can then be processed with metrics are difficult to apply here, even for a single finegative test vectors.

So, I guess my question is, how do you evaluate you best?

Thanks,

Gerardo

Hey Gerardo — I actually cover the answer to that question in my latest blog post. You use the Intersection over Union metric to measure the quality of a detection.

The actual size of the hand doesn't matter as long as the aspect ratio (ratio of width to height) is the same. That is the entire point of applying a sliding window + image pyramid — to detect objects at various scales and locations of an image. I detail a thorough solution to training a custom HOG + Linear SVM object detector inside the PylmageSearch Gurus course. I would suggest starting there.

REPLY 🦴

There are machine learning algorithms that can be trained in batches and sequentially updated — SVMs are not one of them. In this case, you'll need to reduce the size of your training dataset. I would suggest reducing the size of the true negatives and keeping only the most confident hard-negatives.
